

# Detecting positive selection with branch-site codon models (3)

Maria Anisimova

Institute of Computational Life Sciences
Zurich University of Applied Sciences - ZHAW

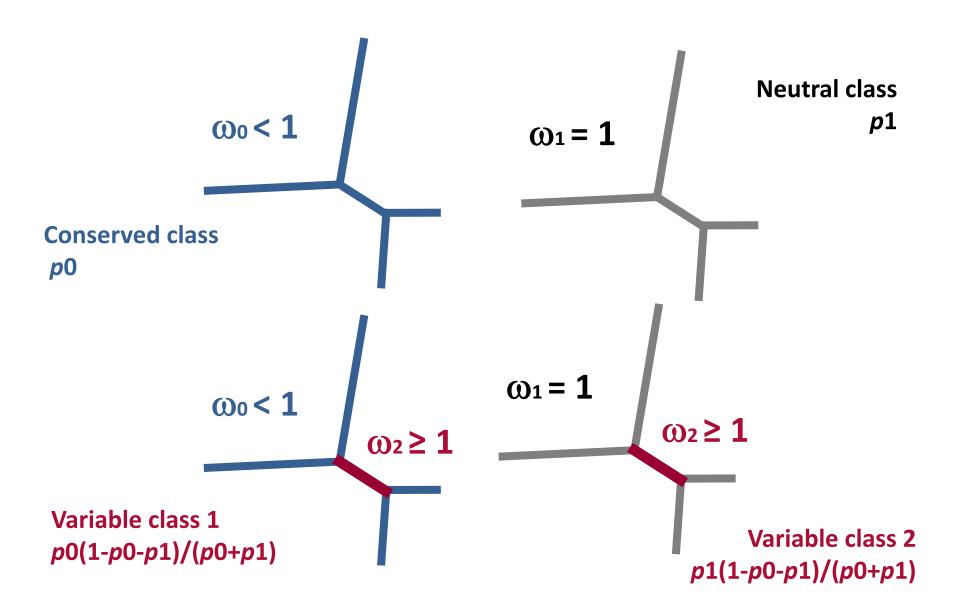

## Modeling selection variability

By modeling variable ω over time and across sites we can study:

WHEN (in which lineages) did positive selection occur?

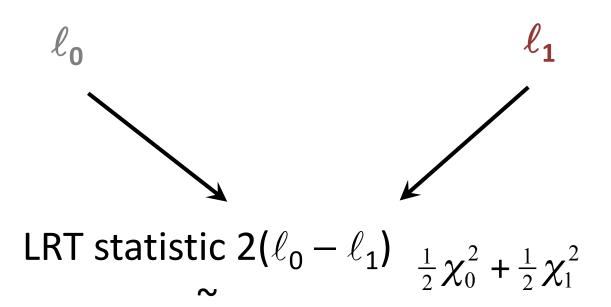

WHERE in the sequence did positive selection occur?

## Branch-site codon model A (Yang et al 2005)

## LRT for positive selection based on branch-site codon model

Null: Model A  $\omega_2 = 1$  fixed Alternative: Model A  $\omega_2 \ge 1$  estimated

Foreground branches (with  $\omega_2$ ) are defined *a priori* 

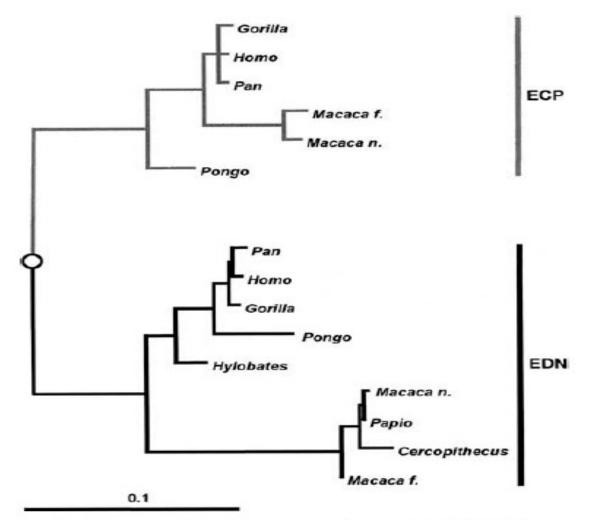

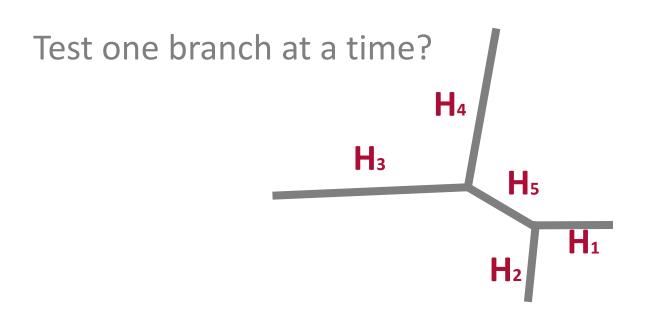

Fig. 3. Gene tree for 15 sequences from the ECP-EDN gene family. The topology was obtained by using maximum likelihood analysis under the HKY85 substitution matrix combined with a correction for among-site rate variation (discrete gamma model). The scale bar indicates the mean number of substitutions per nucleotide site. The open circle indicates the duplication event that gave rise to the ECP and EDN genes. Under Model D, a fraction of sites was allowed to evolve under divergent selection pressure, with  $\omega_{1A}$  and  $\omega_{1B}$  for the two paralogous clades, respectively.

To test for selection

after gene duplication:
branches of one clade
following the duplication
event are set as
foreground

Figure from Bielawski and Yang (2004)

## **Testing multiple hypotheses**

Are  $p_1$ ,  $p_2$ ,  $p_3$ ,  $p_4$ ,  $p_5$  significant at an overall threshold  $\alpha$ ?

Adjust individual thresholds  $\alpha_1$ ,  $\alpha_2$ ,  $\alpha_3$ ,  $\alpha_4$ ,  $\alpha_5$  so overall type I error rate  $\leq \alpha$ 

## Multiple testing correction: FWER or FDR?

Family-Wise Error Rate (FWER): overall type I error (FP rate)

FWER = Pr (reject at least one null when it's true) For n independent true null hypotheses tested at  $\alpha$ : FWER=  $1 - (1 - \alpha)^n$ 

e.g. testing 10 hypotheses at 5% each we may get FWER=40%!

If in some cases the null hypotheses is expected to be wrong, small percentage of false rejections is tolerable

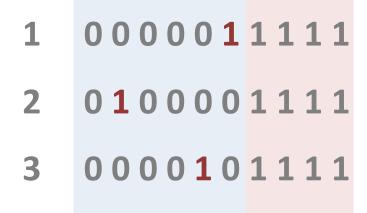

FDR = False Discovery Rate FDR = E(# false rejections/# all rejections)

## **Example: how do FWER and FDR compare**

100 simulated datasets with first 6 null hypotheses true

For each sample, test 10 hypotheses, making 1 error per sample

Test results: 1=sign / 0=not sign

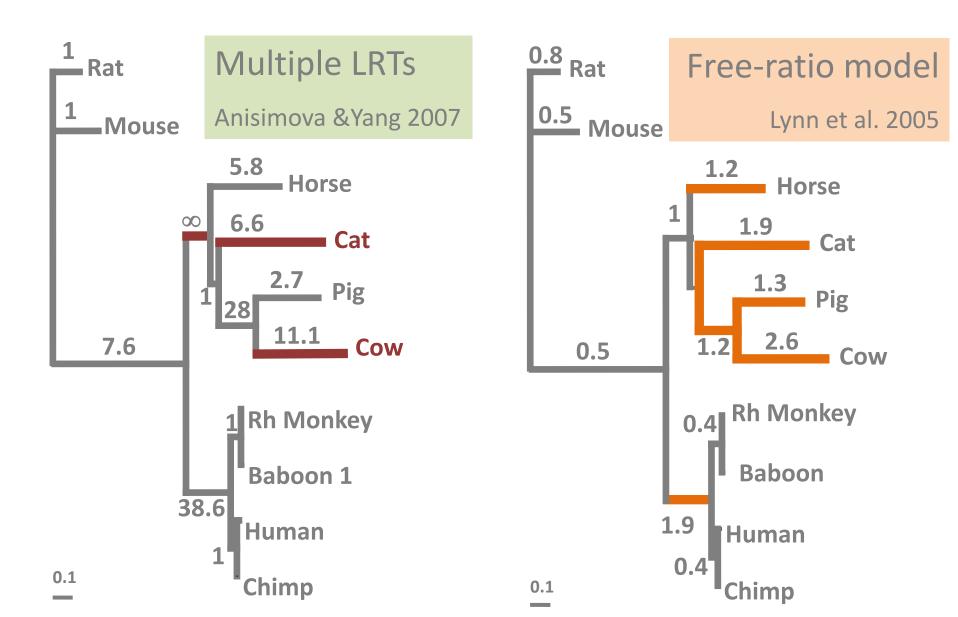

100 0100001111

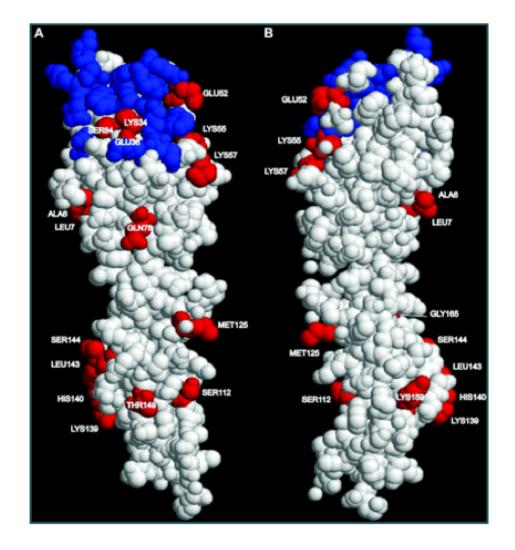

TTTTTTFFFF

**FDR = 20%** 

**FWER = 100%** 

## Multiple branch-site LRTs example: CD2 extra-cellular domain

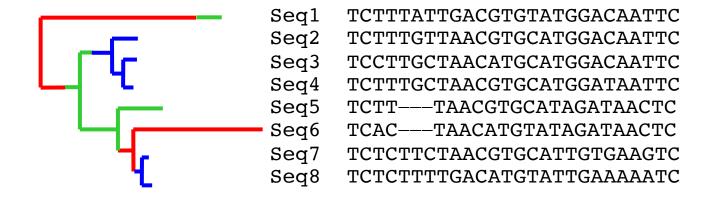

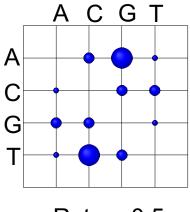

All but two sites under positive selection are found in the extra-cellular domain of CD2

#### FIGURE 3.-

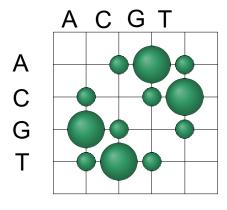

The three-dimensional structure of human CD2 extracellular domain [Protein Data Bank (PDB) http://www.rcsb.org/pdb/entry=1HNF]. Sites shown in red are those sites predicted to be under positive selection (model 8). The sites are labeled according to the numbering scheme used in the PDB file (ALA6 corresponds to site 14 in Table 1). Sites known to be involved in CD58 binding are shown in blue. A and B show two opposite faces of the CD2 molecule. The structure was displayed using RasMol V2.7.2.1.1 (http://www.openrasmol.org/software/rasmol/).

## Alternatively, use covarion models

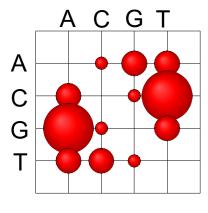

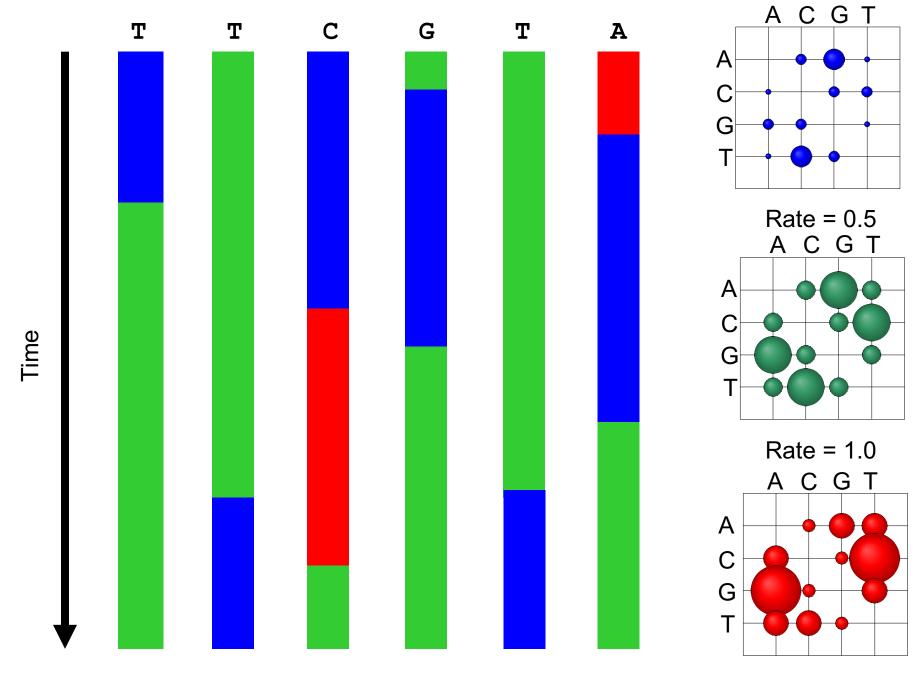

Rate = 1.0

Rate = 2.0

Rate = 2.0

### **Markov Modulated Codon Model**

 $Q_x(ij) = \begin{cases} 0: \text{ if codons } i \text{ and } j \text{ differ at more than one nucleotide position} \\ \omega_x \pi_j: \text{ nonsynonymous transversion} \\ \pi_j: \text{ synonymous transversion} \\ \kappa \omega_x \pi_j: \text{ nonsynonymous transition} \\ \kappa \pi_j: \text{ synonymous transition} \end{cases}$ 

 $Q_x$  describes instanteneous rates for sites from selection regime xCodon models M2 and M3 are considered (each has 3 classes of sites) Guindon et el. 2004 PNAS https://github.com/stephaneguindon/fitmodel

$$\mathbf{R} = \delta \begin{pmatrix} -(p_2 + p_3 \alpha) & p_2 & p_3 \alpha \\ p_1 & -(p_1 + p_3 \beta) & p_3 \beta \\ p_1 \alpha & p_2 \beta & -(p_1 \alpha + p_2 \beta) \end{pmatrix}$$

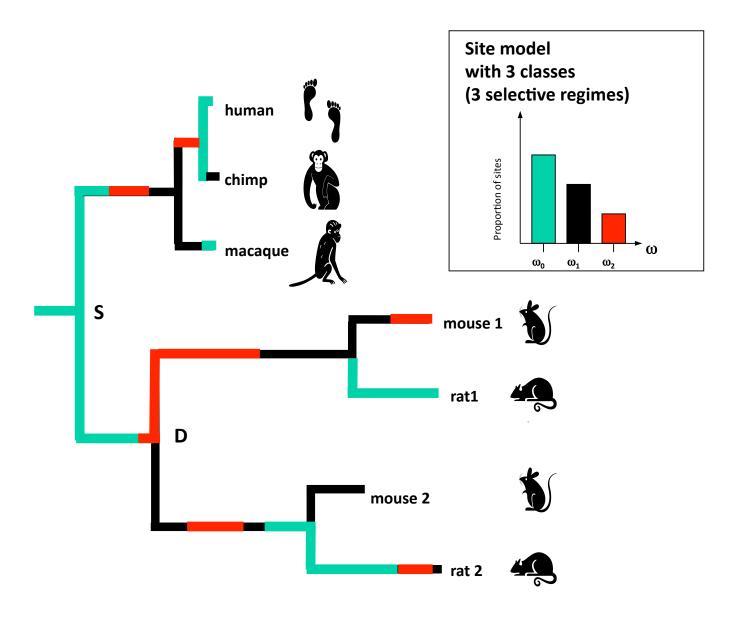

**R** describes rate switches between selection regimes 1, 2 and 3 ( $\omega_1 < \omega_2 < \omega_3$ )  $p_1$ ,  $p_2$ ,  $p_3$  are equilibrium frequencies of sites in each selection regime (add up to 1)  $\alpha$  is relative rate of changes between 1 and 3  $\beta$  is relative rate of changes between 2 and 3

#### Combined process:

$$\mathbf{S} = \begin{pmatrix} \mathbf{Q}_{1} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{Q}_{2} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{Q}_{3} \end{pmatrix} + \delta \begin{pmatrix} -(p_{2} + p_{3}\alpha)\mathbf{I} & p_{2}\mathbf{I} & p_{3}\alpha\mathbf{I} \\ p_{1}\mathbf{I} & -(p_{1} + p_{3}\beta)\mathbf{I} & p_{3}\beta\mathbf{I} \\ p_{1}\alpha\mathbf{I} & p_{2}\beta\mathbf{I} & -(p_{1}\alpha + p_{2}\beta)\mathbf{I} \end{pmatrix}$$

 $\delta$  is the rate of switch between selection regimes

### **Markov Modulated Codon Model**

## LRTs of temporal variation in selection

 $H_0$ :  $\delta$  = 0 (no switches btw regimes or M3)

 $H_1$ :  $\delta \neq 0$ 

 $H_0$ :  $\delta$  = 0 (no switches btw regimes)

 $H_1$ :  $\beta = \alpha = 1$  (switching but no bias in switching pattern)

 $H_0$ :  $\beta = \alpha = 1$  (no bias in switching pattern)

 $H_1: \beta \neq \alpha$ 

Model notations:  $+S1 (\beta = \alpha = 1)$  $+S2 (\beta = \alpha \text{ are free})$ 

## LRTs of temporal variation in selection

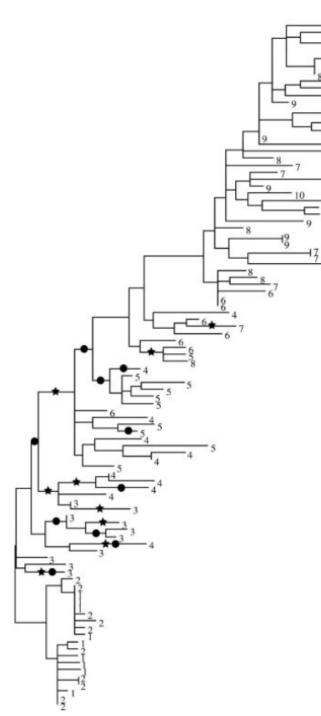

Fig. 1. Phylogenetic positions of substitutions inferred at two amino acid sites of patient 6 data set. M3 strongly supports the hypothesis that sequences evolved under positive selection at these sites, whereas the statistical support given by M3+S1 to the same hypothesis is less important. ★ and ○ correspond to the substitutions inferred at sites 41 and 180, respectively. All of these substitutions are likely to be nonsynonymous. The leaves of the tree are labeled with the rank of the corresponding sample time (1 is the earliest sample and 10 is the latest). The position of the root was determined by using outgroup sequences collected during the earliest stages of the infection.

For each site, the expected time spent in selection class z on the branch of length T, which had selection regime x at the start and y at the end:

$$E[d_{z}(T,x,y)] = \int_{0}^{T} \frac{p_{xz}(t)p_{zy}(T-t)}{p_{xy}(T)}dt$$

where  $p_{xz}(t)$  is the probability of change  $x \to y$  over time t [calculate  $p_{xz}(t)$  from  $P_R(t) = \exp(tR)$ ]

$$Pr(z \mid T, x, y) = E[d_z(T, x, y)]/T$$

This approach is used to detect sites in the alignment where positive selection is likely to have occurred in most of the lineages

## **Exercises with PAML (codeml)**

Focus of exercise #4:

- 1. ML estimation with branch-site models
- 2. Optional: Try out with codon tree (CodonPhyML)
